An industrial robot is an automated machine tool used in the assembly of semiconductor chips and other components. An industrial robot is capable of performing a sequence of tasks automatically, much faster than a human can. An industrial robot is typically an electromechanical device in which one or more motors cause movement and rotation of the robot arm. Currently, the motion of the robot arm is generated by servo motors which are remotely controlled via a cable and a remote control device. The process of assembly on the line requires various tools which are typically mounted on a

pallet, which are used by the robot to assemble the components of the product. It is common for assembly processes to use a part of the robot to load parts from the pallet, move the parts into a desired location, and place the parts into one or more work stations. After it is determined that the part has been assembled correctly, the robot can unload the part from the work station and place the part onto a conveyor for transport to another work station. When a robot is used for manufacturing purposes, the work station that is being used may be a work station that is occupied by a human or a work station that is not occupied by a human. When a robot works in an unoccupied work station, the robot arm is typically not blocked by the assembly parts stored in the unoccupied work station, and may even be able to unload the parts from

the pallet and place the parts into the unoccupied work station. The use of robots for assembly purposes has several advantages over human-controlled processes. For example, assembly lines can be more efficient because robots can perform many repetitive tasks while unoccupied work stations are not being used by a human. In addition, robots are less subject to human error because they are typically highly accurate. Finally, robots can work at higher speeds than human workers, which increases productivity and allows production to be faster and cheaper. The use of industrial robots, however, is not without its drawbacks. Most industrial robots are designed to work in a production line where the parts that are being assembled are typically stored in a single stationary location called a
